

PANSE GROUP

Speed testing results

Testing conditions -

Internet type – Broadband Fiber

Internet speed – 300 Mbps

Number of users on connection – 1

Website -

1. Home page of same website with same plug-ins, code etc has been put to test.
2. The difference between 2 sites, is the availability of webP format for images which reduces file sizes.

Results will vary based on different conditions. Also, the results might not be as drastic in real-life conditions such as mobile network, multiple users on a connection etc., but there will always be a considerable difference

Parameters to look at (look at the dialog box on the right)-

DOMContentLoaded – shown in orange, at the bottom of box: Initial load, where you can see content on the site.

Loadtime – shown in blue, at the bottom of box: Full load of site, where all functionalities are usable. This would be on the higher site for our site, mainly because we are fetching LinkedIn data after site load, and the numbers do not fully represent the reality as the LinkedIn feed is loaded after website data; so, this number will always be on the higher side.

Key Differences -

1. Jellylogic link is on a different server.
2. Jellylogic server has webP image format enabled, which lets us compress the images to a much further extent than usual JPG format, hence file sizes are smaller for content.
3. Quicker DNS resolution, this indicates how quickly the domain was resolved and user was redirected to the website (see screenshots below; the very first row which says “document” as “Type”. The time for each is very different).

First load

Findings-

1. The initial document load or DNS resolution time is high, resulting in slow intialisation of website.
2. The difference in load times due to difference is server is shown as by means of screenshots.

3. The lack of webP on the Pansegroup server, if resolved, would boost the speed up and reduce the load time by at least 10-15%.
